Ambulatory Medical Care Utilization Estimates for 2005

by Catharine W. Burt, Ed.D.; Linda F. McCaig, M.P.H.; and Elizabeth A. Rechtsteiner, M.S., Division of Health Care Statistics

Abstract

Objective—This report presents statistics on ambulatory care visits to physician offices, hospital outpatient departments (OPDs), and hospital emergency departments (EDs) in the United States in 2005. Ambulatory medical care utilization is described in terms of patient, practice, facility, and visit characteristics.

Methods—Data from the 2005 National Ambulatory Medical Care Survey (NAMCS) and the National Hospital Ambulatory Medical Care Survey (NHAMCS) were combined to produce averaged annual estimates of ambulatory medical care utilization.

Results—Patients in the United States made an estimated 1.2 billion visits to physician offices and hospital OPDs and EDs, a rate of 4.0 visits per person annually. Between 1995 and 2005, population visit rates increased by about 20% in primary care offices, surgical care offices, and OPDs; 37% in medical specialty offices; and 7% in EDs. The aging of the population has contributed to increased volume of visits because older patients have higher visit rates. Visits by patients 40–59 years of age represented about 28.5 percent in 2005, compared with 23.9 percent in 1995. Black persons had higher visit rates than white persons to hospital OPDs and EDs, but lower visit rates to office-based primary care and to surgical and medical specialists. In the ED, the visit rate for patients with no insurance was about twice that of those with private insurance; whereas for all types of office-based care, the visit rates were higher for privately insured persons than for uninsured persons. About 29.4 percent of all ambulatory care visits were for chronic diseases and 25.2 percent were for preventive care, including checkups, prenatal care, and postsurgical care. The leading treatment provided at ambulatory care visits was medicinal with 71.3 percent of all visits having one or more medications prescribed, up by 10% since 1995 when encounters with drug therapy represented 64.9 percent of all visits. In 2005, 2.4 billion medications were prescribed or administered at these visits.

Keywords: ambulatory care visits • diagnoses • injury • medications

Introduction

This report presents summary information on the utilization of ambulatory medical care across physician offices and hospital emergency and outpatient departments. Physician offices are further classified by the physician specialty: primary care, surgical, and medical. The tables present total visits across all settings as well as percent distributions by setting type. Data are from NAMCS and NHAMCS, which are part of the ambulatory care component of the National Health Care Survey, a family of provider-based surveys conducted by the Centers for Disease Control and Prevention's National Center for Health Statistics.

Methods

Estimates of ambulatory medical care use are based on national probability provider-based surveys of visits to nonfederal office-based physicians and EDs and OPDs of nonfederal, general, and short-stay hospitals in the 50 states and the District of Columbia. Individual reports are available that contain detailed methods and analyses by setting: *physician*

offices (1), OPDs (2), and EDs (3). These reports, issued annually, provide a comprehensive analysis of visits to ambulatory health care settings in the United States. Estimates of visits are made from a sample of medical record abstracts from each sampled provider during defined reporting periods weighted to provide national annual estimates. More information on the sampling design and scope of the surveys can be found at <http://www.cdc.gov/nchs/about/major/ahcd/ahcd1.htm>.

Results

There were almost 1.2 billion visits to physicians' offices and hospital EDs and OPDs in the United States during 2005, up by 36% in the last 10 years (Figure 1). Between 1995 and 2005, population visit rates increased by about 20% in primary care offices, surgical care offices, and OPDs; 37% in medical specialty offices; and 7% in EDs (Figure 2).

Table 1 presents the 2005 estimates of ambulatory care by setting and patient and geographic demographics.

Table 2 presents visit rates per 100 persons in the civilian noninstitutional U.S. population. Table 3 presents the general kinds of conditions seen, whereas Table 4 presents the leading primary diagnoses for ambulatory care visits, which account for over one-half of all visits. Table 5 presents the number of medications prescribed (both new and continued) at the visits, and Table 6 presents the leading therapeutic classes of the drugs prescribed.

One-half of ambulatory medical care visits (49.0 percent) were to primary care physicians in office-based practices. The rest were to surgical specialists (17.1 percent) and medical specialists (16.3 percent) in office-based practices, and EDs (9.9 percent) and OPDs (7.7 percent) in nonfederal general and short-stay hospitals. The aging of the population has contributed to increased volume of visits because the visit rates are generally higher (excluding infants) for older patients. Visits by patients 40–59 years of age represented about 28.5 percent in 2005, compared with 23.9 percent in 1995 (Figure 3). Starting at age 50, more than one-half of visits were by patients who made three or more visits to their provider in a year and averaged more than two drug prescriptions at each visit (data not shown).

Visit rates for persons with no insurance for the care provided (i.e., expected payment from solely self-pay,

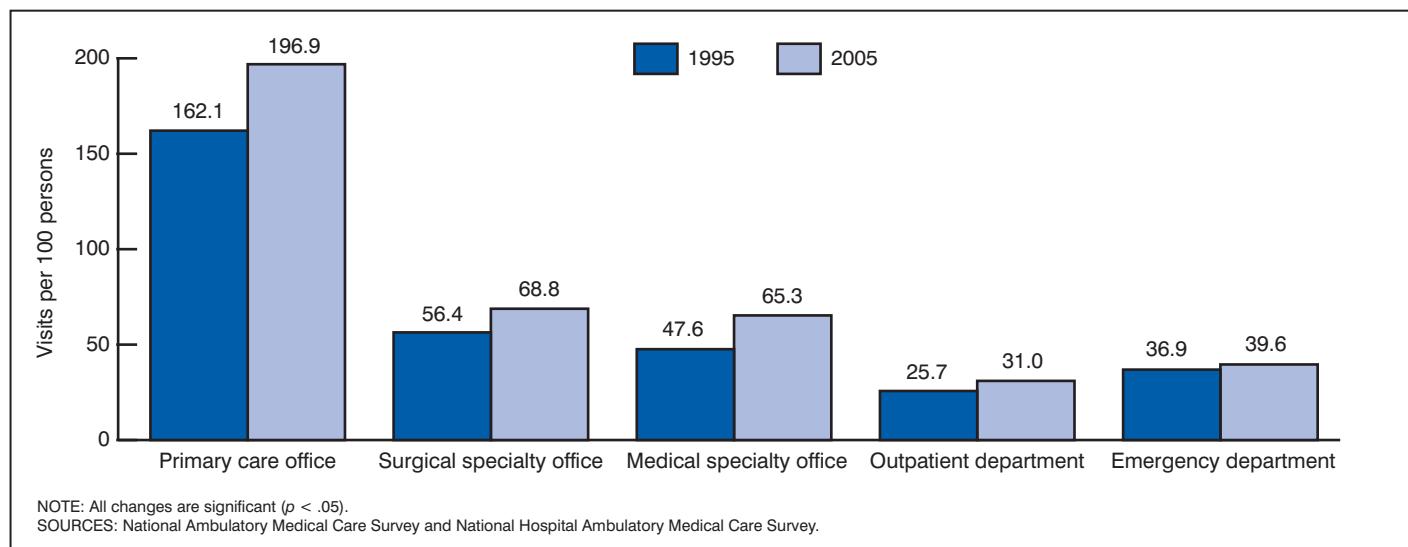

Figure 2. Visit rates by setting type: United States, 1995 and 2005

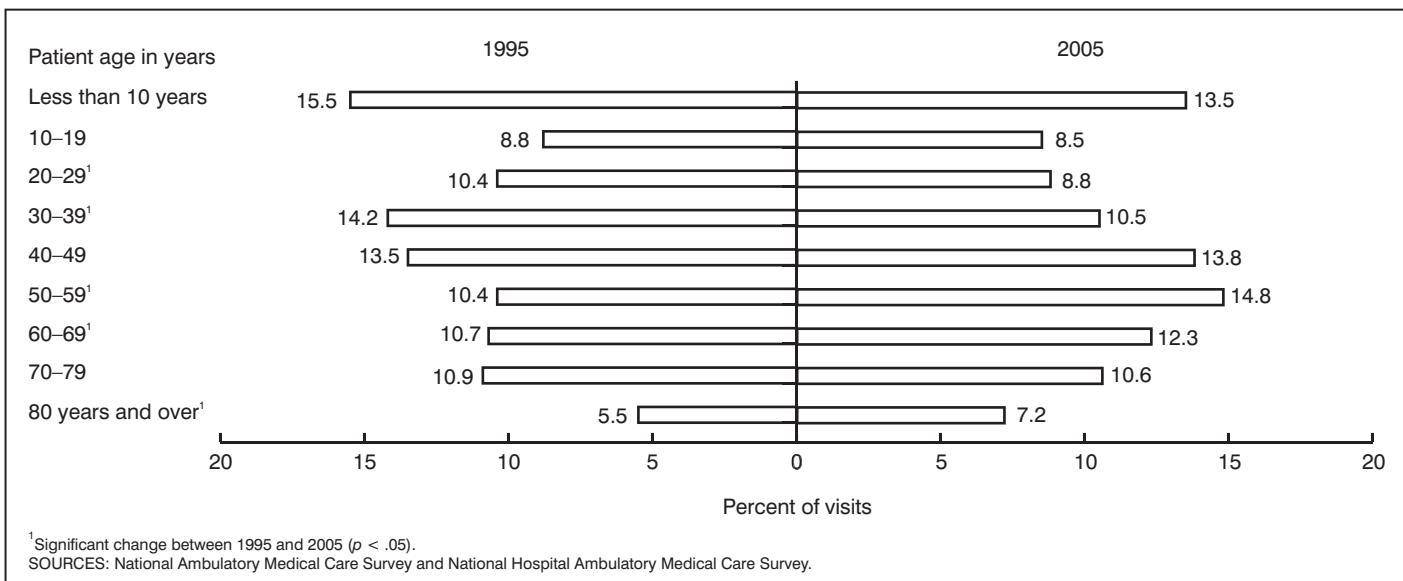

Figure 3. Percent distribution of ambulatory care visits by patient age, according to year: United States 1995 and 2005

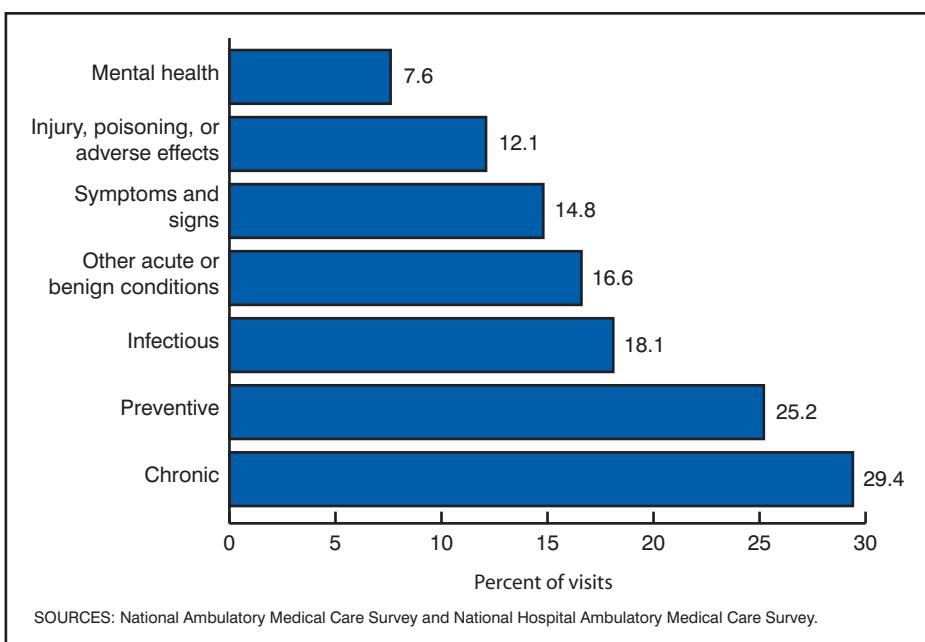

Figure 4. Percentage of ambulatory care visits by type of diseases or conditions seen: United States, 2005

no charge, or charity) were low for all office-based settings than visit rates for persons with various kinds of insurance. In contrast, the visit rate to EDs for the uninsured (45.9 visits per 100 persons) was about twice the rate of persons with private insurance (23.8 visits per 100 persons) (Table 2). The total visit rate for Hispanics (308.4 visits per 100 persons) was lower than that for non-Hispanics (417.4 visits per 100

persons) driven largely by difference in use of office-based physicians as opposed to hospital settings (Table 2). Similarly, black persons had higher visit rates than white persons to hospital OPDs and EDs, but lower visit rates to office-based primary care and surgical and medical specialists.

About 29.4 percent of all visits were for chronic diseases and 25.2 percent were for preventive care, including

checkups, prenatal care, and postsurgical care. About 18.1 percent of visits were for infectious diseases and 12.1 percent were for injuries, poisonings, or adverse effects of medical treatment (Figure 4). The types of patients' conditions varied by setting type (Table 3). EDs were relatively more likely to see injuries and infectious diseases as well as symptoms with no specific diagnosis compared with other conditions. Essential hypertension was the primary diagnosis recorded most frequently (49.2 million) at ambulatory care visits (Table 4), with over three-quarters of these occurring in primary care offices.

The leading treatment provided at ambulatory care visits was medicinal with 71.3 percent of all visits having one or more medications prescribed, up by 10% since 1995 when encounters with drug therapy represented 64.9 percent of all visits. There were 2.4 billion medications prescribed or administered at these visits, including over-the-counter medications, immunizations, allergy shots, anesthetics, and dietary supplements that were newly prescribed or continued (Table 5). Antidepressants, antihypertensives, nonsteroidal anti-inflammatory drugs, hyperlipidemia drugs, and nonnarcotic analgesics were the leading drug classes prescribed, accounting for nearly one quarter

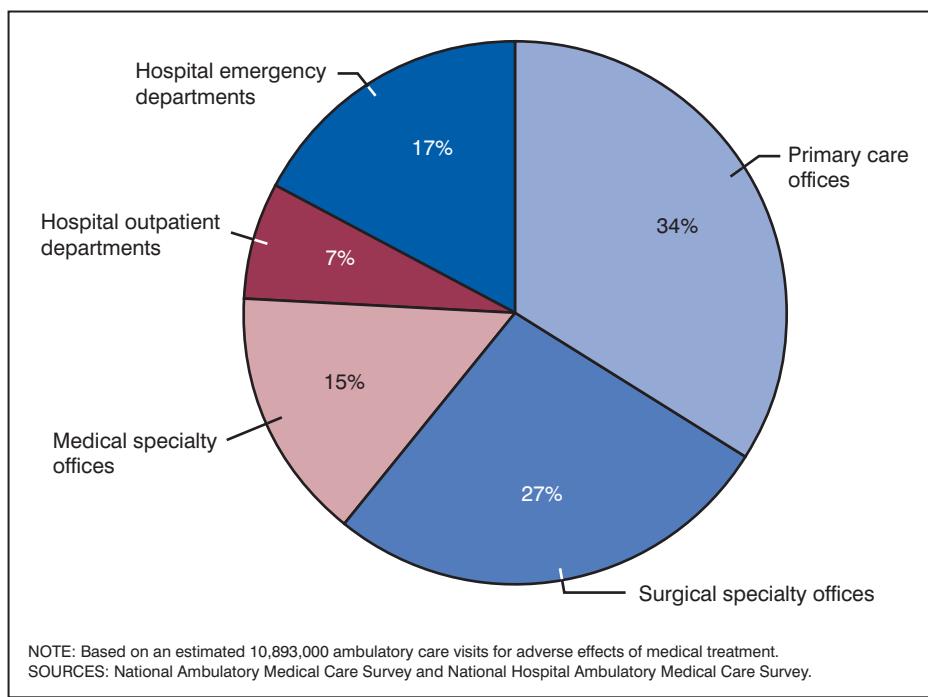

Figure 5. Percent distribution of visits for adverse effects of medical treatment by setting type: United States, 2005

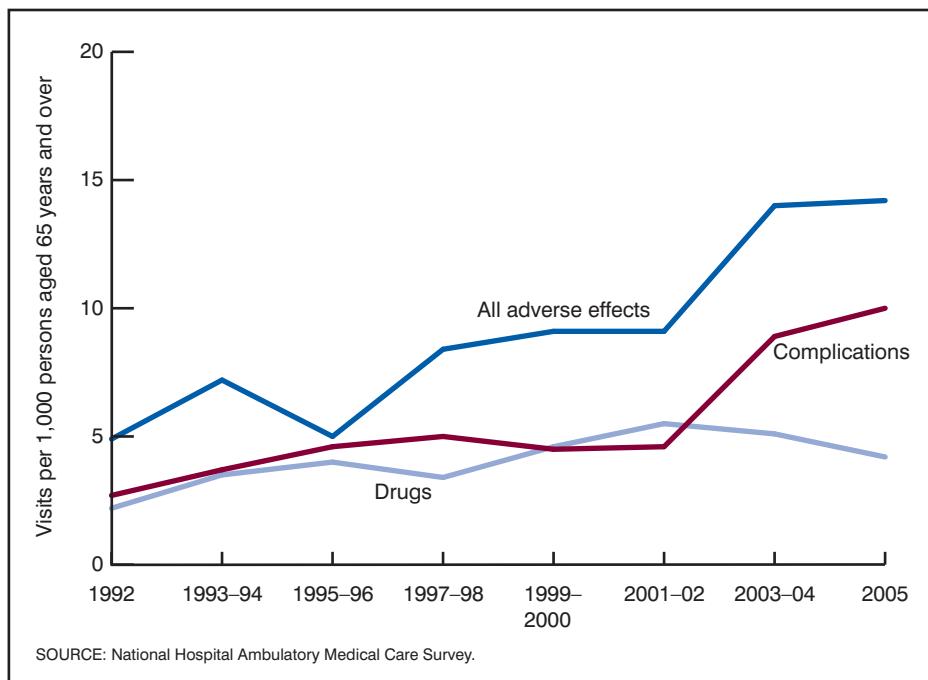

Figure 6. Trends in the rate of visits to emergency departments for adverse effects of medical treatment for persons aged 65 years and over: United States, 1992–2005

(22.9 percent) of all prescriptions (Table 6). Approximately 27.3 percent of medications prescribed or administered at ambulatory care visits in nonemergency settings were for new prescriptions, whereas 72.7 percent were

for continued prescriptions (data not shown).

A small proportion of visits were due to adverse effects of medical treatment (about 1 percent of all visits), which accounted for 10.8 million

medical encounters. These included complications from medical and surgical procedures as well as adverse drug reactions. About 17 percent of visits for adverse effects (Figure 5) were to the ED (1.8 million visits), of which 59.9 percent were for medical and surgical complications and 41.1 percent for adverse drug reactions (data not shown). Among patients aged 65 years and over, adverse effects of medical treatment represented 3.0 percent of ED visits. The rate of ED visits for adverse effects of medical treatment among seniors increased from 4.9 per 1,000 persons in 1992 to 14.2 per 1,000 persons in 2005. The rate has been increasing more for complications of procedures (e.g., surgical-site infection, postoperative bleeding), which had a fourfold increase during this time, compared with the increases in adverse drug reactions that peaked in 2001–2002 (Figure 6). Although the rate of hospital discharges with any procedures has remained fairly constant for seniors during this time frame, their average length of stay has declined by about 40 percent (4). Additionally, the rate of outpatient surgeries for seniors may have increased during this period contributing to more opportunities for complications.

Facility characteristics for physician offices and hospital EDs have been recently published. Public-use microdata visit files for 2005 are available for download from <http://www.cdc.gov/nchs/about/major/ahcd/ahcd1.htm>.

* Figure does not meet standard of reliability of precision.

¹The race groups, white, black or African American, Asian, Native Hawaiian or other Pacific Islander, American Indian or Alaska Native, and multiple races, include persons of Hispanic and not Hispanic origin. Persons of Hispanic origin may be of any race. Starting with data year 1999, race-specific estimates have been tabulated according to 1997 Standards for Federal Data on Race and Ethnicity and are not strictly comparable with estimates for earlier years. The percentage of visit records with multiple races indicated is small and lower than is typically found for self-reported race in household surveys.

²SCHIP is State Children's Health Insurance Program.

³Includes self-pay or no charge or charity visit where no other payment sources were listed.

⁴MSA is metropolitan statistical area.

^{*} Figure does not meet standard of reliability of precision.¹ Visit rates for age, sex, race, and region are based on the July 1, 2005, set of estimates of the civilian noninstitutionalized population of the United States as developed by the Population Division, U.S. Census Bureau.² Population estimates of metropolitan statistical area status are based on data from the 2005 National Health Interview Survey, National Center for Health Statistics, adjusted to the U.S. Census Bureau definition of core-based statistical areas as of December 2005. See <http://www.census.gov/population/www/estimates/metrodef.html> for more about metropolitan statistical definitions.³ Population estimates for expected source of payment are based on data from the 2005 National Health Interview Survey.⁴ The race groups, white, black or African American, Asian, Native Hawaiian or Other Pacific Islander, American Indian or Alaska Native, and multiple races, include persons of Hispanic and not Hispanic origin. Persons of Hispanic origin may be of any race. Starting with data year 1999, race-specific estimates have been tabulated according to 1997 Standards for Federal Data on Race and Ethnicity and are not strictly comparable with estimates for earlier years. The percentage of visit records with multiple races indicated is small and lower than is typically found for self-reported race in household surveys.⁵ SCHIP is State Children's Health Insurance Program.⁶ No insurance defined as having only self-pay or no charge or charity as payment sources.⁷ MSA is metropolitan statistical area.

Table 3. Number and percentage of visits for type of condition by type of ambulatory care setting: United States, 2005

* Figure does not meet standard of reliability or precision.

... Category not applicable.

¹Based on the standard four-digit drug classification used in the *National Drug Code Directory*, 1995 edition.

²Total of all therapeutic classes will exceed total number of drug mentions because up to three classes may be coded for each drug.

³Based on an estimated 2,430,234,000 drugs mentioned at ambulatory care visits (up to eight per visit) in 2005.

⁴NSAIDs are nonsteroidal anti-inflammatory drugs.

⁵ACE is angiotensin-converting enzyme.

NOTE: Numbers may not add to totals because of rounding.
